

Based Upon: PCT/EP2003/006090

REMARKS

Applicants respectfully request entry of the above Preliminary Amendment to place this U.S. Patent Application in better form for examination and prosecution before the U.S. Patent and Trademark Office.

The claims have been amended to eliminate multiple dependent claims and to more definitely and fully claim the subject matter of Applicants' invention. Applicants urge that the above Preliminary Amendment introduces no new matter into this U.S. Patent Application.

Applicants sincerely believe that this U.S. Patent Application is now in condition for examination and prosecution before the U.S. Patent and Trademark Office.

Respectfully submitted,

Printing Device

BACKGROUND OF THE INVENTION Field of the Invention

^{This}
[The] invention relates to a printing device with an electro-photographic print unit, to which a transfer medium for transferring a toner powder to a substrate in a transfer zone is assigned, wherein the substrate can be conducted through the transfer zone by [means of] a transport system, ^{and} [wherein] heat energy can be introduced into the substrate by [means of] one or several heating elements.

Discussion of Related Art

[Such a] ^A printing device is known from [USP] 5,988,068. There, an endlessly revolving belt is assigned to an electro-photographic print unit as the transfer medium. A photoconductor rolls off on the belt for transferring an image ^{made} [consisting] of toner powder. The toner image can be applied to a substrate. [To this end, the] ^{The} substrate is moved ^{beyond} [past] the transfer medium by [means of] a transport system. [In this case the] ^{The} transfer medium rolls off the substrate surface to be imprinted. For improving the toner transfer, [USP] 5,988,068 proposes the employment of two heating elements. The first heating element heats the substrate to a temperature higher than 60°C. The second heating element acts on the transfer medium at a temperature higher than 100°C.

[With this] ^{This} arrangement ^{is} [it has been found to be] disadvantageous, in particular in connection ^{because} with printing with ceramic toners, [that] residue from the toner adheres to the transfer medium which, because of the doughy consistency, is hard to remove at this temperature, or cannot be completely removed. ^{Also} [Moreover], during constant operation, heat is introduced into the electro-photographic print unit via the transfer medium. This ^{which} results in [the worsening of the] ^{lesser} image quality.

SUMMARY OF THE INVENTION

It is ^{one}the object of ^{this}the invention to ^{provide}create a printing device of the type mentioned ^{has}above but [at the outset, by means of] which an improved toner transfer from the transfer medium to the substrate [is possible].

This object is [attained in that] ^{achieved with}a cooling device [is] assigned to the transfer medium, which removes heat from the [latter]. Because of the cooling of the transfer medium, ^{transfer medium}[it is assured that] the toner powder does not adhere to the surface of the transfer medium after [the] transfer to the substrate [has been] ^{is}completed, but instead is released almost completely during the transfer. The introduction of heat into the print unit, in particular at the sensitive photoconductor, is also prevented by the cooling, or is at least minimized to an acceptable degree.

In accordance with ^{one}a preferred embodiment (variation) of ^{this}the invention, [it has been provided that at] ^{near}the transfer zone formed with the substrate, the transfer medium has a lower temperature, [at least in the area of] ^{or near}the contact face, than the surface of the substrate. It ^{is}has then been assured that the flow of heat can ^{occur}take place at most from the substrate to the transfer medium. Then the cooling device removes this heat in a controlled manner, at least in the greatest part.

In accordance with ^{this}the invention, [it can be provided that] the cooling device cools the temperature of the transfer medium to a temperature $\leq 60^{\circ}\text{C}$. The temperature preferably is less than 40°C . At these temperatures the transfer medium is not heated, even during constant operation, [in such a way] ^{so}that the toner powder reacts with the surface of the transfer medium. The toner transfer can ^{also}be additionally aided in that ^{assisted if}the toner transfer in the transfer zone can be affected by [means of] one or several coronas. In the course of this,

during which

electrostatic forces act on the toner powder. For example, it is possible to arrange coronas over large areas upstream and/or downstream of the transfer zone. These then charge the substrate. Alternatively, or additionally, the substrate can also be placed on a conductive base. In contrast to negatively charged toners, the ^{toners are} [latter is] then positively charged. With positively charged toners then correspondingly negatively ^{the} [charge voltages can be reduced in an advantageous manner ^{so} [in such a way] that negative field effects, such as with an exclusive toner transfer created by [means of] electrostatic fields, no longer occur.

An additional improvement of the toner transfer can be achieved ^{if} [in that] ^{on its} [surface] which receives the toner powder the transfer medium ^{has} [is provided with] an anti-adhesive layer, and that this anti-adhesive layer ^{with} [has] a surface energy within the range of 15 mN/m to 30 mN/m.

It ^{is possible} [would be conceivable] to use a Teflon coating within the range of 18 to 20 mN/m. In this case the anti-adhesive layer should have a layer thickness in a range between 1 and 100 μm , preferably 5 to 50 μm . A particularly effective heating of the substrate can ^{occur if} [take place in that] the substrate can be charged with heat energy by [means of] a heating element designed as an infrared radiator and/or a hot air blower and/or by [means of] the application of a flame. The substrate should be heated in a temperature range between 80°C and 200°C. In a preferred manner, the surface temperature of the substrate in the coating area ^{is} [has been] set to more than 100°C to 170°C. In this case, the temperature should be set as a function of the toner used. Tests with ceramic toners having a solids component (pigments, glass frit) of 50 to 70% ^{show} [have shown] that a surface temperature of the substrate of 120°C to 150°C is particularly advantageous. Following the conclusion of the transfer, the

toner powder should melt onto the substrate. If the toner powder ^{is} [has been] completely melted, a subsequent fixation can possibly be omitted.

On [the] one hand, the print medium can consist of a matrix of thermoplastic material, into which organic or inorganic color pigments and/or glassy paste particles can be introduced for coloration.

In another case, the plastic matrix ^{is} [consists] of a mixture of hardening and binder resins, or of polymers which, at temperatures $> 100^{\circ}\text{C}$, are reacted to form thermosetting [i.e.] ^{such as} spatially cross-linked, structures, into which again organic or inorganic color pigments can be introduced for coloration.

[Moreover], ^{Also} other additives can [also] be contained in it, such as conductive particles or particles of mechanically resistant material, for example, which later [on] result in an electrically conductive coating or a protective layer against scratches, for example.

Matched to the substrate to be imprinted, it ^{may} [can] be necessary to maintain the substrate temperature as low as possible. This is of importance in particular ^{particularly} in connection with temperature-sensitive plastic substrates or with glass which is less resistant to temperature changes. In this case it is necessary to adapt the plastic matrix of the print media [in such a way] ^{so} that the softening point of the matrix is also lowered. This is of particular interest when, in the case of additives such as ceramic pigments or glass paste particles, the softening temperature rises with an increased proportion of solids in the plastic matrix.

Some examples of toners with ceramic color and glass paste additions: ^{include}

Toner 1: Proportion of solids 44 wt-% *and* Softening [temp.] *temperature of* 98°C ;

Toner 2: Proportion of solids 58 wt-% *and* Softening [temp.] *temperature of* 104°C ;

Toner 3: Proportion of solids 71 wt-% *and* Softening [temp.] 113°C .

A reduction of the softening temperature in case of an increased proportion of solids is provided, on the one hand, by adding polymer additives, such as wax, or by using a different low-melting plastic matrix.

The indicated softening temperatures relate to measurements by *[means of]* a Shimazu viscosity measuring device Type CFT-500 c.

[Measuring conditions:]		Supported weight	10 kg
	→	Nozzle diameter	0.5 mm
		Nozzle length	1 mm
		Plunger surface	1 cm ²
		Start temperature	80°C
		Heating rate	3 k/min]

To achieve a control of the substrate temperature, ^{it can be provided that} a temperature sensor ^{can be} ~~is~~ assigned to the substrate, and ~~that~~ the heating element and/or the transport system can be controlled by ~~means of~~ a control device as a function of the signal emitted by the temperature sensor.

In this case the temperature can be regulated by acting on the transport system via the retention time of the substrate in the heating zone, or via the speed of its passage.

Regulation preferably ^{occurs when} ~~takes place in that~~ the substrate enters the transfer zone ~~always~~ at a constant surface temperature. During the transfer, the substrate surface should be evenly heated.

To achieve an effective heat regulation of the transfer medium, ^{it can be provided that} one or several liquid-cooled contact rollers of the cooling device roll off on the transfer medium, ^{and/or that} a climate-controlled air flow is directed onto the surface of the transfer medium.

It is also ^{possible} ~~conceivable~~ for the transfer medium to be ^{embodied as} a transfer roller which contains at least a portion of the cooling device. ^{Thus} ~~In this case~~ the cooling device can also contain one or several Peltier elements. Alternatively or additionally, the transfer roller can also be water-cooled or air-cooled.

If ^{it is provided that} the cooling device removes heat energy from the transfer medium downstream of the transfer zone and upstream of the photoconductor of the print unit in the transport direction of the transfer medium, ^{then} the introduction of heat into the photoconductor is ^{reliably} ~~dependably~~ prevented.

BRIEF DESCRIPTION OF THE DRAWINGS

^{This} [The] invention ^{is} [will be] explained in greater detail in [what follows by means] ^{view} of an exemplary embodiment represented in the drawings. Shown are in

Fig. 1 ^{shows} a printing device in a schematic representation;

Fig. 2 ^{shows} a transfer medium with an associated cooling device, ^{also} in a schematic representation; and

Fig. 3 ^{shows} a transfer medium with interior cooling, ^{in a schematic representation}.

DESCRIPTION OF PREFERRED EMBODIMENTS

A printing device with an electro-photographic print unit 30 is represented in Fig. 1. ^{and} It has a cylinder-shaped photoconductor 32. It is provided with a uniform charge on ^a [its] surface in a charge station 31.1. This charge is then partially removed again in a subsequent discharge station 31.2. A developer unit 33 applies toner powder to the charged areas of the surface of the photoconductor. The toner image ^{thus} developed [in this way] is transferred to a transfer medium 34 in a transfer zone. The basic structure of the transfer medium 34 designed as a transfer roller ^{is shown} [can be seen] in greater detail in Fig. 2. As illustrated in this representation, ^{where} the transfer medium 34 has a roller base body 34.1. A resilient, electrically semi-conducting intermediate layer 34.2 ^{is} [has been] applied to ^{the} [this] roller base body 34.1. This can contain, for example, silicon, EPDM or polyurethane. An anti-adhesive coating 34.3 is arranged indirectly or directly above the intermediate layer 34.2. [It constitutes] ^{and for} the roller surface.

As Fig. 1 ^{further} shows, a transport system 10 is arranged below the transfer medium 34. ^{and} It has a number of roller bodies, on which a substrate 13 can be conveyed. The transport system 10 ^{is} [has been] arranged [here in such a way] ^{so} that the transfer medium 34 rolls off on the surface of the substrate 13 to be imprinted. In the process, the toner powder on the

transfer medium is transferred to the substrate 13. To ^{assist} aid the toner transfer, a corona 12 ^{is} has been integrated into a roller body of the transport system 10, which is arranged directly underneath the transfer zone.

One or several heating elements 24 ^{each is} [is/are] arranged upstream of the transfer medium in the transport direction of the substrate 13. They ^{and acts} act on the surface of the substrate 13 ^{to} and heat it evenly to a temperature within the range between 100°C and 170°C. One or several temperature sensors 21 are arranged between the heating elements 24 and the transfer medium 34 for monitoring the temperature. These ^{and} emit a temperature signal to one or several regulating devices 22. ^{Each} The regulating device 22 reads in a predetermined value via a control device 23. The predetermined value is compared with the temperature signal in a comparator circuit. The heating elements 24 can be adjusted in ^{the event} (case) of a temperature difference. The transport speed of the transport system 10 in the area upstream of the transfer medium 34 can also be regulated ^{Thus} [to support this]. [It is assured in this way that] the substrate 13 always enters the transfer zone with an approximately constant surface temperature.

A cooling device 35 is assigned to the transfer medium 34. ^{and} It has one or several water-cooled rollers, which are in surface contact with the transfer medium 34. The rollers are connected with a heat-regulating unit 36, which removes heat energy from the transfer medium 34. The water coming from the rollers is conducted to the heat-regulating unit 36 via a circulation system. ^{and} It is cooled in the temperature unit 36, ^{and is} then returned back to the rollers.

A further embodiment ^{variation} of a cooling device 35 is represented in Fig. 2. ^{and} This has an air supply conduit 35.1. A gaseous cooling medium, preferably air, can be

blown through the ^{air supply conduit 35.1} [latter] onto the surface of the transfer medium 34. The air removes heat energy from the transfer medium 34. The heated fluid flow can then be aspirated off again via an air-return conduit 35.2. The air-return conduit 35.2 prevents the creation of gas flows outside the cooling zone, which can lead to damage to the toner image maintained on the transfer medium 34 or the photoconductor 32.

In a further embodiment, the core of the transfer roller ^{can be} [consists for example] of a material of good heat conductivity, such as copper, aluminum or ceramic materials, such as SiC or Si₃N₄, for example, and is possibly provided with cooling ribs, such as represented in Fig. 3, and is cooled by an air flow through the interior of the transfer roller. The core is coated with a flexible material of 1 to 2 mm thickness and of good heat conductivity, such as PTFE, FPM, silicon, or PUR plastic material filled, for example, with glass or a mineral material, for example.

A transfer belt with an interior blower ^{can} [is] ^{be used} [also [conceivable], so that cooling of a large area by [means of] a relatively small air flow is possible.

It is advantageous if zone heating is provided over the print width [in such a way] ^{so} that the heat output in each of the edge areas is regulated separately from the center zone. This has ^{one} [the] advantage, that the surface temperature can be better controlled over the print width and ^{thus} [therewith] the temperature ^{can be} constant over the print width ^{and} can be improved. [To this end, ^{thus} respective individual control devices ²² (22) and temperature sensors ²¹ (21) are assigned to each zone heating element. In this case the temperature sensors ²¹ (21) ²¹ advantageously ^{are} [consist] of pyrometers which detect the surface temperature of the substrate ¹³ (13). A temperature constant of ± 5 K should be attempted ^{there} [there].

A further embodiment provides that the substrates to be imprinted are heated in a separate, upstream-located temperature process. This takes place, for example, in a continuous throughput oven with ambient air heaters.
